

A constant extra correction matches or exceeds the full-information score

Saved development results only | same fixed ridge | 26 source-local groups in 3 evaluation components

Full residual information Condition-only residual information
Global / constant residual information

Dashed line: nominal 95% region | Ridge observed coverage: 100%

Uniform point-error improvement is not established. Ridge still uses the actual observations and condition.

Global correction beats matched full-information NLL by 0.628 / 1.039 / 6.398. This does not show that measured input is unnecessary.

The previously exposed evaluation informed the follow-up design. No generalization, biological mechanism or physical-parameter claim.

Constant correction is defined in standardized/asinh space; inverse-sinh can still produce input-dependent covariance in original units.
